

REAL TIME ACTIVE NETWORK COMPARTMENTALIZATION

ABSTRACT OF THE DISCLOSURE

Security policy manager devices are leveraged by manager objects to use highly secure user transparent communications to provide detection of questionable activities at every node, automatic collection of information related to any potential attack, isolation of the offending object with arbitrary flexibility of response (e.g. flexibly determining the level of certainty of an attack for initiation of a response in accordance with the number of nodes to be partitioned that is determined by the collected data concerning the potential attack), changing trust relationships between security domains, limiting the attack and launching offensive information warfare capabilities (e.g. outbound from the compromised node while limiting or eliminating inbound communications) in log time and simultaneously and/or concurrently in different but possibly overlapping sections or segments of a digital network of arbitrary configuration.
